(Thales Digital Factory, France)

BSides Athens 2024

Summary of the talk

1 Introduction: APT Context

- 2 What Is Malicious Cryptography & Mathematics?
- How to Bypass Dynamic Code Analysis
- 4 Short-keys Deniable Cryptography
- 5 Bypassing Data Leak Prevention

Agenda

1 Introduction: APT Context

- 2 What Is Malicious Cryptography & Mathematics?
- 3 How to Bypass Dynamic Code Analysis
- 4 Short-keys Deniable Cryptography
- 5 Bypassing Data Leak Prevention
- 6 Conclusion

GENERAL DISCLAIMER

Any views or opinions presented in this talk are personal and are the results of my own research work. They belong solely to the speaker and, in any case, they do not represent those of people, institutions, companies or organizations that the speaker may or may not be associated with in professional or personal capacity (including past, present and future employers).

- This research work was conducted from mid-2019 to end of 2020.
- All codes and PoC developed are **TLP:RED** (responsible disclosure).

Introduction: Working Environment & Scenarios

CYBERSECURITY DIVE Deep Dive Library Events Press Releases

Strategy Breaches Vulnerability Cyberattacks Threats Leadership & Careers Polis

DIVE BRIEF

National Cyber Director echoes past warnings: Nation-state cyber threats are mounting

State-linked actors with ties to China and Russia are growing more sophisticated in their efforts to disrupt critical infrastructure, Harry Coker Jr. said during a CyberUK conference keynote.

Published May 15, 2024

- We focus in our talk to APT or Nation state attacks.
 - Optimization of the risk/effort ratio.
 - The worst risk is to be detected and identified.
- From the defender perspective, the analysis and safeguards are
 - Automated or semi-automated analysis.
 - Manual/ad hoc analysis.

- The attacker has to face several critical issues than can trigger alerts and block malware action:
 - 11 Data may be analysed so semantic detection (keywords, statistical profile, Data Leak Prevention [DLP]) can be enforced.
 - 12 Encrypting data before exfiltration is likely to be detected (entropy profile test, however rarely in place)
 - 13 Encryption implies a secret key (can be recovered during malware analysis or during the process performing the data exfiltration).
 - 14 Malware binary code may be analysed and reverse-engineered.
 - I5 Known exfiltration techniques (steganography, covert channels) drastically limit the amount of data to exfiltrate without detection (up to a few kilobytes)
 - 16 Users' behaviours may be analysed to detect suspect actions betraying data exfiltration.
- Any analysis by the defender must be defeated.

- Explore the potential of malicious cryptography & mathematics.
- Evaluate and assess forthcoming approaches by malware designers (APT threats, state malware).
 - Especially, assess risk far beyond already existing identified threats (such *Lambload, VerbleCon...*)
- Identify and test possible mitigation techniques.
- We present "unitary attack bricks" for clarity but they can be combined in whole or in part.

Introduction: APT Context

What Is Malicious Cryptography & Mathematics?

3 How to Bypass Dynamic Code Analysis

- 4 Short-keys Deniable Cryptography
- 5 Bypassing Data Leak Prevention
- 6 Conclusion

Malicious Cryptology & Mathematics

- Malicious Cryptology and Malicious Mathematics (MCMM) is an emerging domain initiated in (Filiol, 2012)
 - Generalization of Young & Yung's (2004) crypto virology Young (limited case of extortion malware/ransomware).
- MCMM defines the interconnection of attack techniques with cryptology and mathematics for their mutual benefit. Covers several fields and topics (non exhaustive list):
 - Development "super malware" able to evade any kind of detection by implementing:
 - Optimized propagation and attack techniques (e.g. by using biased or specific random number generator).
 - Sophisticated self-protection techniques (malware code and operations protection thanks to strong cryptography-based tools).
 - Partial or total invisibility features. The programmer intends to make his code and actions to become invisible by using statistical simulability

Malicious Cryptology & Mathematics (continued)

- Use of complexity theory or computability theory to design undetectable malware.
- Use of malware to perform cryptanalysis operations (steal secret keys or passwords), manipulate encryption algorithms to weaken them on the fly in the target computer memory. The resulting encryption process will be easier to break/bypass.
- Recon in target environments (e.g. processor-dependent malware)
- Design and implementation of encryption systems with hidden, undetectable mathematical trapdoors (see a real instance in [Filiol & Bannier, BlackHat Europe, 2017]).

See bibliography slide for extended references [1].

2 What Is Malicious Cryptography & Mathematics?

How to Bypass Dynamic Code Analysis

- 4 Short-keys Deniable Cryptography
- 5 Bypassing Data Leak Prevention
- 6 Conclusion

• We consider a two-step attack.

- A malware precursor is deployed. It does not contain malicious functions so far. It gathers technical information on the target (intelligence step) and sends it to a Command & Control (C&C).
- The C&C constantly analyses data provided by the precursor and malware to evaluate whether they are under analysis or not.
- The C&C updates, modifies and provides data to the malware as often as required for the attack evolution.

• We consider a two-step attack.

- A malware precursor is deployed. It does not contain malicious functions so far. It gathers technical information on the target (intelligence step) and sends it to a Command & Control (C&C).
- The C&C constantly analyses data provided by the precursor and malware to evaluate whether they are under analysis or not.
- The C&C updates, modifies and provides data to the malware as often as required for the attack evolution.

• Malware and C&C communicate through a buffer neutral zone (mutating IPs, protection of the C&C). Use of a sophisticated protocol to manage potentiel analysis on target size.

• We consider a two-step attack.

- A malware precursor is deployed. It does not contain malicious functions so far. It gathers technical information on the target (intelligence step) and sends it to a Command & Control (C&C).
- The C&C constantly analyses data provided by the precursor and malware to evaluate whether they are under analysis or not.
- The C&C updates, modifies and provides data to the malware as often as required for the attack evolution.
- Malware and C&C communicate through a buffer neutral zone (mutating IPs, protection of the C&C). Use of a sophisticated protocol to manage potentiel analysis on target size.
- The precursor evades detection (it does not contain actual malicious functions). Subsequent modifications aim at providing persistence without detection.

Secure Clueless Protocol (precursor/malware side)

- Module M: computes complex mathematical functions (processor fingerprint [1]). Results v_i and computation time t_i are sent to the C&C.
 - For instance $sin(10^{37}\pi_j)$ where π_j are different precision values of π .
 - A lot of possible functions and precision levels enable a very accurate processor fingerprint.

Secure Clueless Protocol (precursor/malware side)

- Module *I*: gathers technical data (and the collection time) on the local target:
 - CPUID, HD Serial numbers, MAC address, SID, GUID, RAM fingerprint, Thermal status...
 - The collection time for each parameter is also sent.
- Module V: compute a virtualization detection index according to [4].
- Upon completion, the precursor self-modifies (operate and forget).
 From now on any analysis would reveal nothing.

Secure Clueless Protocol (C&C side)

- The C&C analyses data collected and build a target computation model $\mathcal{M}_{\mathcal{T}}$.
 - $\mathcal{M}_{\mathcal{T}}$ can be compared to a reference model database.
 - *M_T* enables the C&C to build and use further clueless challenges for the malware at times fixed by the C&C.
 - $\mathcal{M}_{\mathcal{T}}$ is not simulable.
- The actual encrypted malware is pushed to the precursor.

Attack Management Protocol

- Precursor self-updates with the malware code (actual attack part is encrypted).
- Environmental data are used to request frequent computations from the malware.
 - Random computation and data gathering (values and computation time) wrt modules *M*, *I* and *V*.

Activation Protocol

Activation Protocol

1. Malware computes $H^{k}(d)$ from d and k and check whether it equals activation data α .

- 2. Sends result and computing time t to C&C 3. if α then load and operates M I & V and send results and computing time to C&C
- 4. otherwise do nothing.

(Thales Digital Factory, France)

BSides Athens 2024

Activation Protocol

Step 2

- I. Malware computes $H^{k}(d)$ from d and k and check whether it equals activation data α .
- 2. Sends result and computing time t to C&C 3. if α then load and operates M 1 & V and send results and computing time to C&C
- 4. otherwise do nothina

Introduction: APT Context

- 2 What Is Malicious Cryptography & Mathematics?
- 3 How to Bypass Dynamic Code Analysis
- 4 Short-keys Deniable Cryptography
- 5 Bypassing Data Leak Prevention
- 6 Conclusion

Non-Trivial Deniable Cryptography: Principles

- Building effective encryption algorithm to realize **practical** deniable cryptography was until very recently still an open problem.
 - Only known case is trivial (one-time pads or OTP).
 - Since the "keys" are as long as the two (or more) plaintexts, not a valid solution (OTPs must be hardcoded).
- Let *C* be a ciphertext of length *N*, a **unique** algorithm *E* and any two different arbitrary plaintexts P_1 and P_2 . We built a C framework to build encryption algorithms (within seconds from given plaintexts) enabling effective deniable cryptography with short keys (128 256 bits).
 - *E* is a deterministic encryption algorithm (stream cipher or block cipher). It is supposed to be public and therefore resistant to known cryptanalysis techniques. Keys are *k*-bit long. No secret element hardcoded.
 - k is far smaller than N (so OTPs not considered).
 - We have $C = E(K_1, P_1) = E(K_2, P_2)$
 - The scheme can be extended to a finite number of plaintexts P_i

Non-Trivial Deniable Cryptography: Applications

- The cryptographic security analysis of these algorithms have confirmed the resistance against the following attacks:
 - Guess P_1 and P_2 from the ciphertext C (in other words, retrieving keys K_1 and/or K_2).
 - Find P_1 knowing P_2 and conversely.
- Awesome number of applications:
 - Code protection against static and dynamic analysis (see next slide).
 - Anti-forensics techniques.
 - Multiple communication channels in a single one (flow deniable cryptography).
 - ...
- Demo...

Deniable Cryptography-based Malware

• The most critical part of the malware is encrypted (C). Needs an external key from the C&C to operate.

Deniable Cryptography-based Malware

• The most critical part of the malware is encrypted (C). Needs an external key from the C&C to operate.

- Transform data with an encryption algorithm and a secret key into a random data.
- Accessing plaintext data is supposed to be practically intractable without the key.

• Secret key-dependent encryption and random insertion to hide a message into an innocent-looking cover without altering (too much) its statistical profile.

Cryptography versus Steganography: detection

- Detection of cryptography is straightforward using the entropy profile [2].
 - Plaintext data: entropy $H(X) \approx 4$
 - Packed/compressed data: *H*(X) ≈ 6
 - Encryption data: H(X) = 8

- Beyond an insertion rate of 0.03, detection is efficient with modern techniques [3]
- Size of secure payload is limited (to √n; n is the number of usable coefficients for embedding).

Entropy and Statistical Profile Mimicking

- Data to exfiltrate exhibit entropy profile $H(\mathcal{D}_d)$ (e.g. *.pdf files)
- Data to mimic exhibit entropy profile $H(\mathcal{D}_t)$ (e.g. *.text files).
- We then compute a priori an intermediate (transition) entropy profile $H(\mathcal{D}_l)$ such that $H(\mathcal{D}_t)$ is the joint entropy profile $H(\mathcal{D}_d, \mathcal{D}_l)$ (here $H(\mathcal{D})$ describes the entropy profile of source data with distribution \mathcal{D}).

Without loss of generalities, let us consider the following text to evade

THIS IS A SECRET MESSAGE IN TEXT

The result of transformation toward different text distributions gives:

- Second-order Markov character distribution HEMB THAT WILSDOM ABOARICE AMOLL ELETS XEDEAT GIRLS ESSE OFTE AGENT
- First-order Markov word distribution gives ACTING THIS AND BEARING SECRET DEFENSE IS A NATURAL AGE IN METHOD OF TEXT FOR THE LETTERS IN MESS BE THOSE

Here we achieve nearly 30 % of embedding rate (similar to concept of steganographic rate) without detection.

- Examples of the previous slides are perfect against any automated analysis BUT might be detected by human analysis (infeasible in practice however but possible during forensics steps)
- With more complex models and distributions, we succeeded in defeating even manual analysis (reading)
 - However, depending on the target distribution (target data profile), the embedding rate may drops to 8-10 % (which still better than steganography).
- **Demo**: critical database exfiltration (1494 bytes)
 - 128-bit key dependent transformation
 - Target distribution: FW log language
 - Target file of 8852 bytes (embedding rate of 17 %, no optimization)
 - FW log files are prone to be exchanged outside

30 / 36

• There exist a quite infinite number of possibilities:

- You can change the language (English to French for instance)
- You can change the format (TEXT to WORD or PDF). Care about some tags to avoid errors however.
- You can make the distribution order vary...
- Note that the higher the distribution order the lower the data rate.
- Preventing this is impossible. It would require to recode/transcode any data before transmission preventively and by default (computing resources issues).
- No DLP tool is able to detect this nowadays and will likely never.

- DLP techniques also rely on behavioural analysis (frequency, volume, nature or format of documents, etc.). They must be taken into account.
- Similar approach requiring to analyse the main behavioural distributions used in DLPs.
 - These distributions are often public or known.
 - A malware can analyse specific distributions in a preliminary identification/intelligence phase.

Introduction: APT Context

- 2 What Is Malicious Cryptography & Mathematics?
- 3 How to Bypass Dynamic Code Analysis
- 4 Short-keys Deniable Cryptography
- 5 Bypassing Data Leak Prevention

- The potential of MCMM is huge and is bound to almost systematically defeat pure technical solutions and mitigations.
- The defender faces complexity and computing issues especially if the malware embeds adaptative behaviours and techniques.
- The huge potential of MCMM is very likely to see new malware technologies arise very soon (if not already for APTs).
- Prior security assessment, secure architecture, data assessment, tight rights management are necessary to lower the issues but in no way sufficient.
- Suitable security policies should be adopted especially whitelisting techniques (including time fencing, geofencing, portknocking...)
